

Life History & Ecology of the Wood Stork (*Mycteria americana*)

Hart Rufe, St. Lucie Audubon

Dr. Shawn Liston
Research Manager, SW Region

Wood Stork

Mycteria americana

“Wood Ibis”

- Only stork species currently breeding in the U.S.
- Largest breeding colony in the northern hemisphere @ Corkscrew Swamp Sanctuary
- LENGTH: 33 ½ - 45 ½ inches
- WINGSPAN: 59 – 69 inches
- WEIGHT: 72 – 93 ounces (4 ½ - 5 ¾ lbs)

Wood Stork

Mycteria americana

- Often take advantage of atmospheric thermals – conserves energy (16.0 J/m flapping vs. 1.9 J/m soaring)
- Heights over 1,000 m; travel over 40 km to feeding sites
- When thermal updrafts are strong, WOST can glide 16-24 km (10-15 mi) with wings motionless

COLONY SITES

- Freshwater & marine-estuarine forested habitats
- Inundation of trees deters nest predation

- Monogamous
- Pair bonds likely do not endure for more than a single season
- No apparent site fidelity from year to year
- Male establishes nest site and courts females
- Courtship lasts hours to days
- Male usually initiates nest construction

- Most often nest in mixed-species colonies (esp. ANH, GREG, GBH)
- Clutch size: 2-5 eggs
- Male & female tend nests (equally)
- If 1 adult is lost or abandons, other adult may incubate 2-3 days before abandoning
- Incubation lasts 27-32 days
- Nests attended by at least 1 parent full-time until chicks are ~20 d old
- Young 50-60 d old begin to leave nest
- Fledge rate varies: average 1.2-2.9 fl/nest

HOW TO ID

DISTRIBUTION

MIGRATION

NESTING

FEEDING

DIET

ECOLOGY

IMPACTS

**These little guys grow quickly
and need lots of food...**

FEEDING SITES

- Natural & artificial wetlands (water depth 10-30 cm)

- Feed using TACTILOCATION (sim. to WHIB, GLIB, ROSP)
- WOST bill snap is one of the fastest reflex actions among vertebrates (~25 milliseconds)
- Often use foot-stirring and/or wing-flicking
- Feed singly, in groups, in single-file lines, in mixed species aggregations

ENERGY REQUIREMENTS

- Chicks require ~16.5 kg food from hatching to fledging
- Adults require ~0.52 kg/bird/d (courtship, nest building, incubation, caring for chicks) x 120 d
- Small colony (100 pairs): 2 adults/nest fledging 1.5 fledglings/nest requires **~15,000 kg of food**
- 1961 & 1966 CSS colony (6,000 pairs) required 440 lbs food/nest = **~2.6 million kg of food**

(estimates probably low- do not consider many factors)

■ Quite particular about water depth & prey density

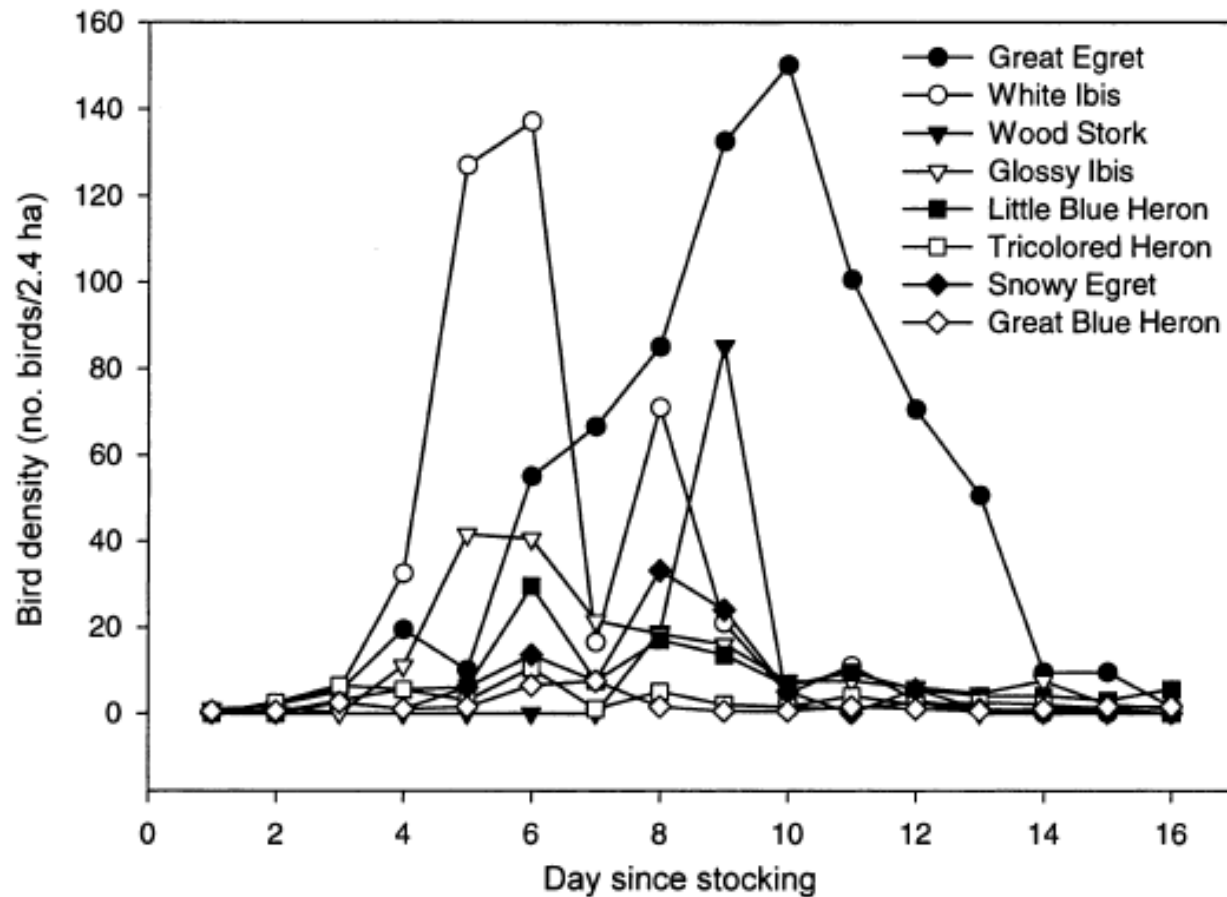

FIG. 4. Daily mean bird density over time varied by species (all treatments pooled). Density was low on day 7 because of rain.

(Gawlik 2002)

■ Appear to remove larger prey first

Frequency distributions of fish length (SL, mm) collected in 1-m² throw trap on successive days of heavy wading bird foraging

“Day 1” = 3/13/09, “Day 4” = 3/16/2009 (bars represent 1 mm size classes)

- Not true prey preference (tactile feeders cannot be selective)
- Likely an artifact of prey behavior

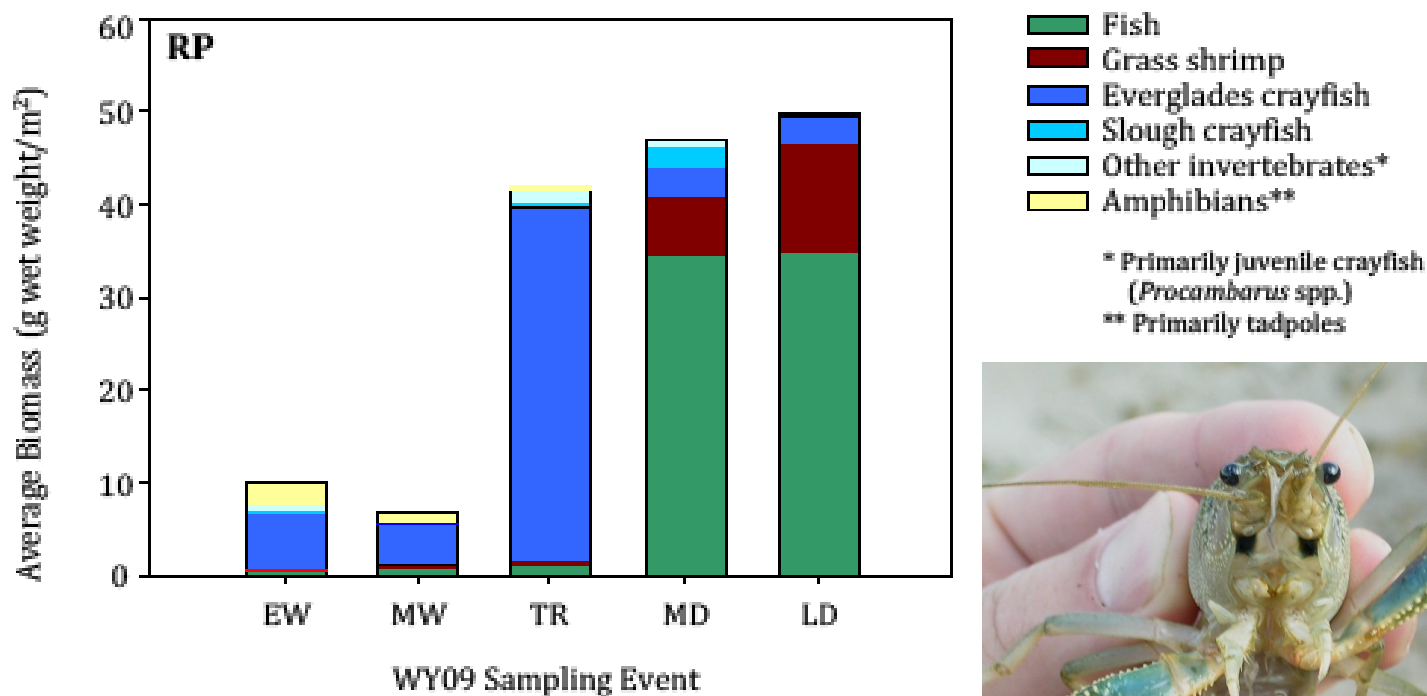

- Literature suggests diet is primarily fish
- Ideally: fish 2-10 cm

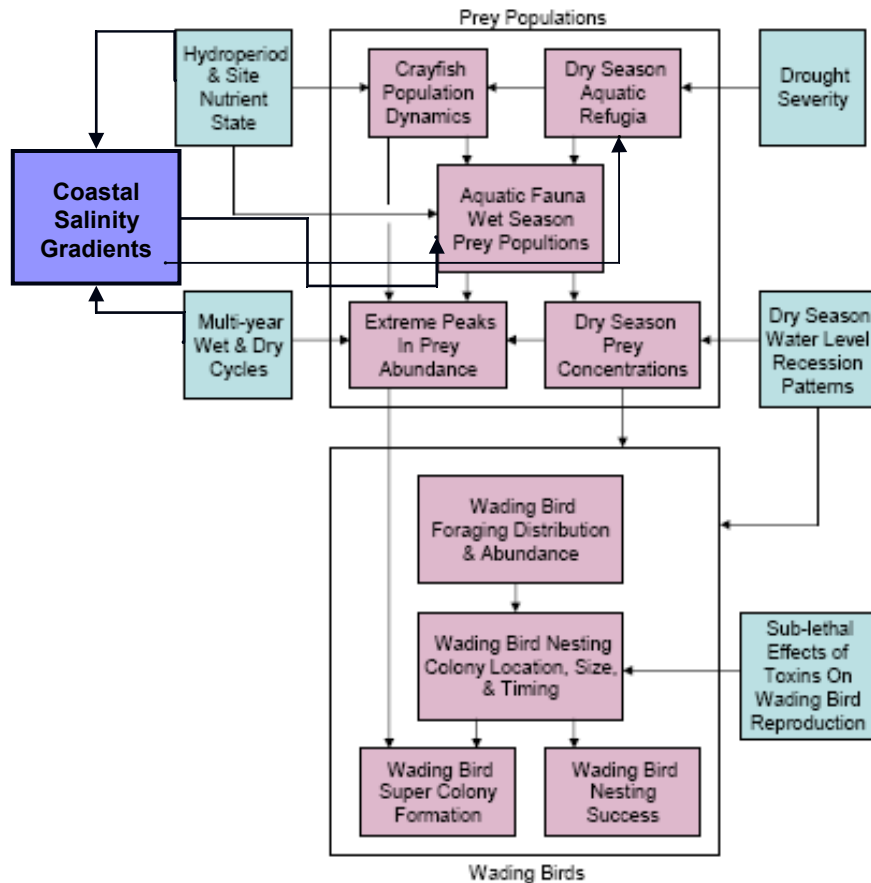

- Opportunistic: also consume plant material, insects, snails, crayfish, grass shrimp, amphibians, reptiles, small mammals, mammal dung

- Our data suggest crayfish are likely an important diet component in the wet season (October-January)

CONCEPTUAL ECOLOGICAL MODEL

WET SEASON

Most of the
landscape is
inundated

Aquatic fauna
are dispersed
throughout the
system

As water levels
recede, fish
instinctively
move toward
deeper areas

DRY SEASON

Fauna become
trapped in refuges

Wading birds &
other predators
take advantage of
high prey density

Crayfish burrow
underground

- From flat sheetflow with shallow dimpled pools to a patchwork of ditches, roads, dikes, deep lakes.
- This systemic alteration has degraded wetland ecology - from primary productivity to top predators

IMPACTS

Short Hydroperiod Wetlands provide a critical function for Wood Storks and other wading birds

- Wetlands available for foraging in Nov/Dec - short hydroperiod wetlands
- Productivity plummeted as a result of loss of Nov/Dec foraging habitat
- Major shift in nest initiation from Nov/Dec to Jan/Feb in late 70's
- Preservation/restoration of Nov/Dec wetlands is vital to Stork recovery

Future WOST population trends in South Florida

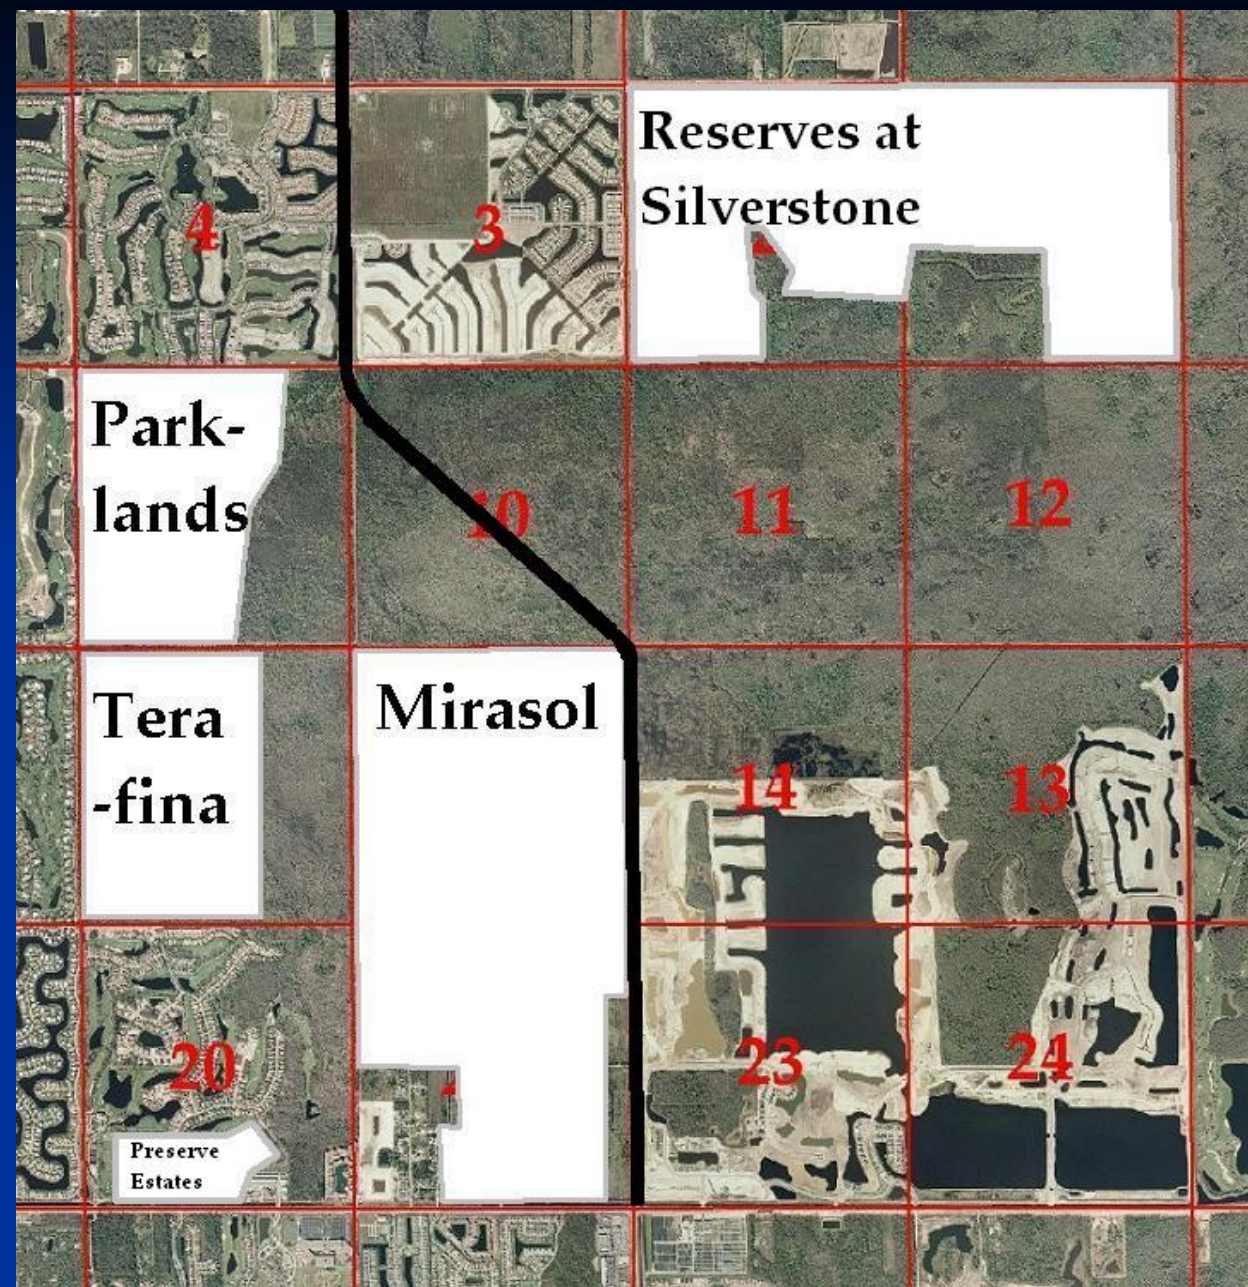

If they initiate nesting early (Nov-Dec)

28% increase over next 30 years

If they continue to nest late (late Jan-Mar)

38% decrease over next 30 years

(unpublished data, Rena Borkataria, UF)

Pressure to develop these few remaining short hydroperiod wetlands increases threat to WOST in SW FL
